Abstract

The Resource Assessment and Conservation Engineering Division of the Alaska Fisheries Science Center conducts annual bottom trawl surveys to monitor the condition of the demersal fish and crab stocks of the eastern Bering Sea continental shelf. The standard study area encompasses a major portion of the eastern Bering Sea shelf between the 20-m and the 200-m isobaths and from the Alaska Peninsula north to approximately the latitude of St. Matthew Island ($60^{\circ}50'N$). In 2008, two chartered trawlers, the 40-m FV *Arcturus* and the 40-m FV *Aldebaran* surveyed this area. Demersal populations were sampled by trawling for 30 minutes at stations centered within 37.04×37.04 km (20×20 nautical mile) grids covering the survey area. At each station, species composition of the catch was determined, and length distributions and age structure samples were collected from ecologically and commercially important species.

Three-hundred seventy-five of the 376 standard survey stations were sampled successfully. A total of 83 species of fishes representing 19 families and 54 genera as well as 174 species of invertebrates representing 12 phyla were identified in the catches from the entire survey area. The combined biomass of walleye pollock, yellowfin sole, and rock sole was 8.1 million metric tons (t) which was 75% of the total fish biomass. The biomass of invertebrates was composed primarily of echinoderms (1.6 million t) and crustaceans (0.75 million t).

Survey results presented in this report include abundance estimates for fishes and invertebrates, geographic distributions and size composition of principal fish species, and contour plots of surface and bottom temperatures during the survey sampling period. Appendices provide station data, summarized catch data by station, species listings, and detailed analyses of abundance and biological data of the sampled populations.

Introduction

The eastern Bering Sea continental shelf supports one of the most productive groundfish and crab fisheries in the world (Bakkala 1993). Since 1970, groundfish such as walleye pollock (*Theragra chalcogramma*), yellowfin sole (*Limanda aspera*) and Pacific cod (*Gadus macrocephalus*) have been the primary target species among commercial catches. Although many species of groundfish are caught commercially, walleye pollock is the most abundant with catches ranging from 1.2 to 1.5 million metric tons (t) per year for the past 30 years, and marketed products represent 40% of the global whitefish market (Ianelli et al. 2008).

Since 1971, the National Marine Fisheries Service (NMFS) Resource Assessment and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC) has conducted an annual bottom trawl survey in the eastern Bering Sea to determine the distribution and abundance of groundfish and crab resources.

The first large-scale survey of the eastern Bering Sea shelf was conducted in 1975 under contract from the U.S. Bureau of Land Management in response to a need for baseline data to assess the potential impact of proposed offshore oil exploration and development on fishery resources (Pereyra et al. 1976). During this baseline survey, sampling was conducted over the eastern Bering Sea shelf between the 20-m and 200-m isobaths from the Alaska Peninsula north to approximately 62°N.

In subsequent years, the area coverage of the annual surveys was reduced until 1979 when the most comprehensive survey of the Bering Sea shelf was undertaken in cooperation with the Japan Fisheries Agency (Bakkala and Wakabayashi 1985). That survey encompassed the entire region sampled in the 1975 baseline study plus the continental slope waters between

St. Matthew and St. Lawrence Islands. A hydroacoustic survey was also conducted in 1979 to assess the midwater component of the walleye pollock population.

Subsequent annual bottom trawl surveys have essentially resampled the stations established during the 1975 survey, with slight modifications each year. This region encompasses the major portion of economically important eastern Bering Sea groundfish and crab populations, except those primarily located in the deep continental slope waters. Commercial crab stocks managed by the Alaska Department of Fish and Game (ADF&G), are covered by the North Pacific Fishery Management Council's (NPFMC) Fishery Management Plan for the Commercial King and Tanner Crab Fisheries in the Bering Sea and Aleutian Islands Regions. Crab species of interest include Tanner crab (*Chionoecetes bairdi*), snow crab (*C. opilio*), two stocks of blue king crab (*Paralithodes platypus*), red king crab (*P. camtschaticus*), and hair crab (*Erimacrus isenbeckii*). Detailed results from the analysis of crab data from this survey are available in Chilton et al. (2008).

Beginning in 1979 and on a triennial basis through 1991, the survey was extended to include bottom trawl sampling of the continental slope and in the region between St. Matthew and St. Lawrence Islands. The continental slope was not surveyed from 1992 to 1999 but was resumed in 2000 as an independent bottom trawl survey series that is surveyed on a biennial basis (Hoff and Britt 2005). The most recent continental slope survey was conducted in 2008.

The groundfish information gathered by the annual biological surveys serves to: 1) provide annual fishery-independent estimates of abundance and biological condition of commercially exploited stocks to the NPFMC; 2) provide updates on the distribution and abundance information to commercial fishermen; and 3) continue a time-series database critical to our improved understanding of the population dynamics and interactions of groundfish

species. This report presents information collected by the AFSC on the eastern Bering Sea shelf during the 2008 bottom trawl survey, which represents the twenty-seventh contribution to the time series.

Methods

Survey Area and Sampling Design

The standardized eastern Bering Sea bottom trawl survey is based on a systematic design with a fixed sampling station at the center of each 37.04×37.04 km (20×20 nautical mile) grid square (Fig. 1). In areas surrounding St. Matthew and the Pribilof Islands, a high-density sampling of “corner stations” was implemented to better assess local blue king crab concentrations (Fig. 1). The original sampling design included 356 sampling stations that were sampled annually starting in 1982. Beginning in 1987, 20 additional stations in Strata 82 and 90 were added to the survey (Fig. 2) to investigate the distribution and abundance of opilio crabs and the northern distribution of walleye pollock. All results reported herein include data analyses for all 376 stations combined.

Sampling Logistics and Stratification Scheme

Survey trawl sampling began in Bristol Bay and stations were sampled along alternate, longitudinal columns (Fig. 2). When possible, using two vessels, this pattern of sampling proceeded westward to the shelf edge. This practice was designed to balance the coverage of the survey area between vessels. The progression from east to west was established in response to movements by yellowfin sole and perhaps other species, which may be migrating eastward during the course of the survey (Smith and Bakkala 1982).

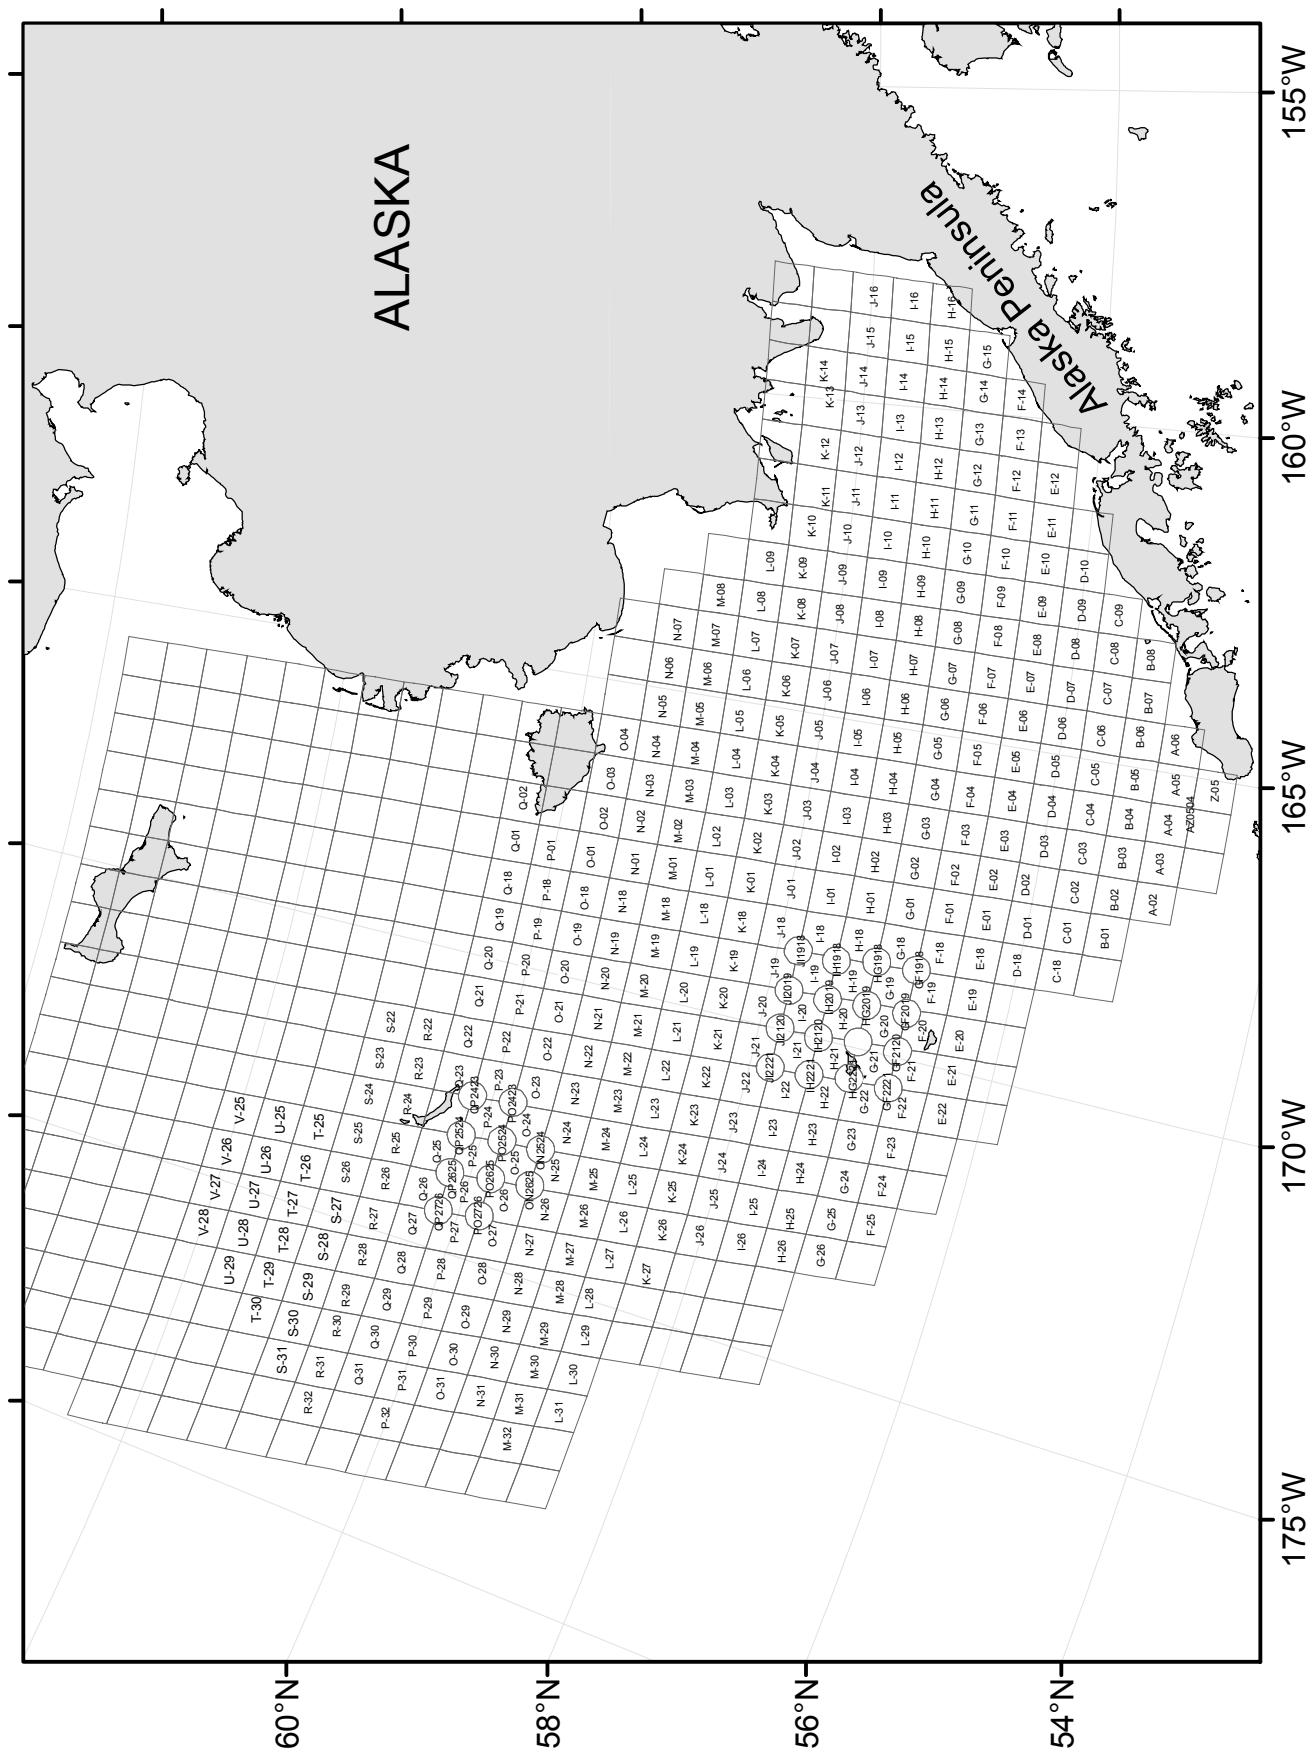

Figure 1. -- Grid map of sample stations for the 2008 eastern Bering Sea continental shelf bottom trawl survey.

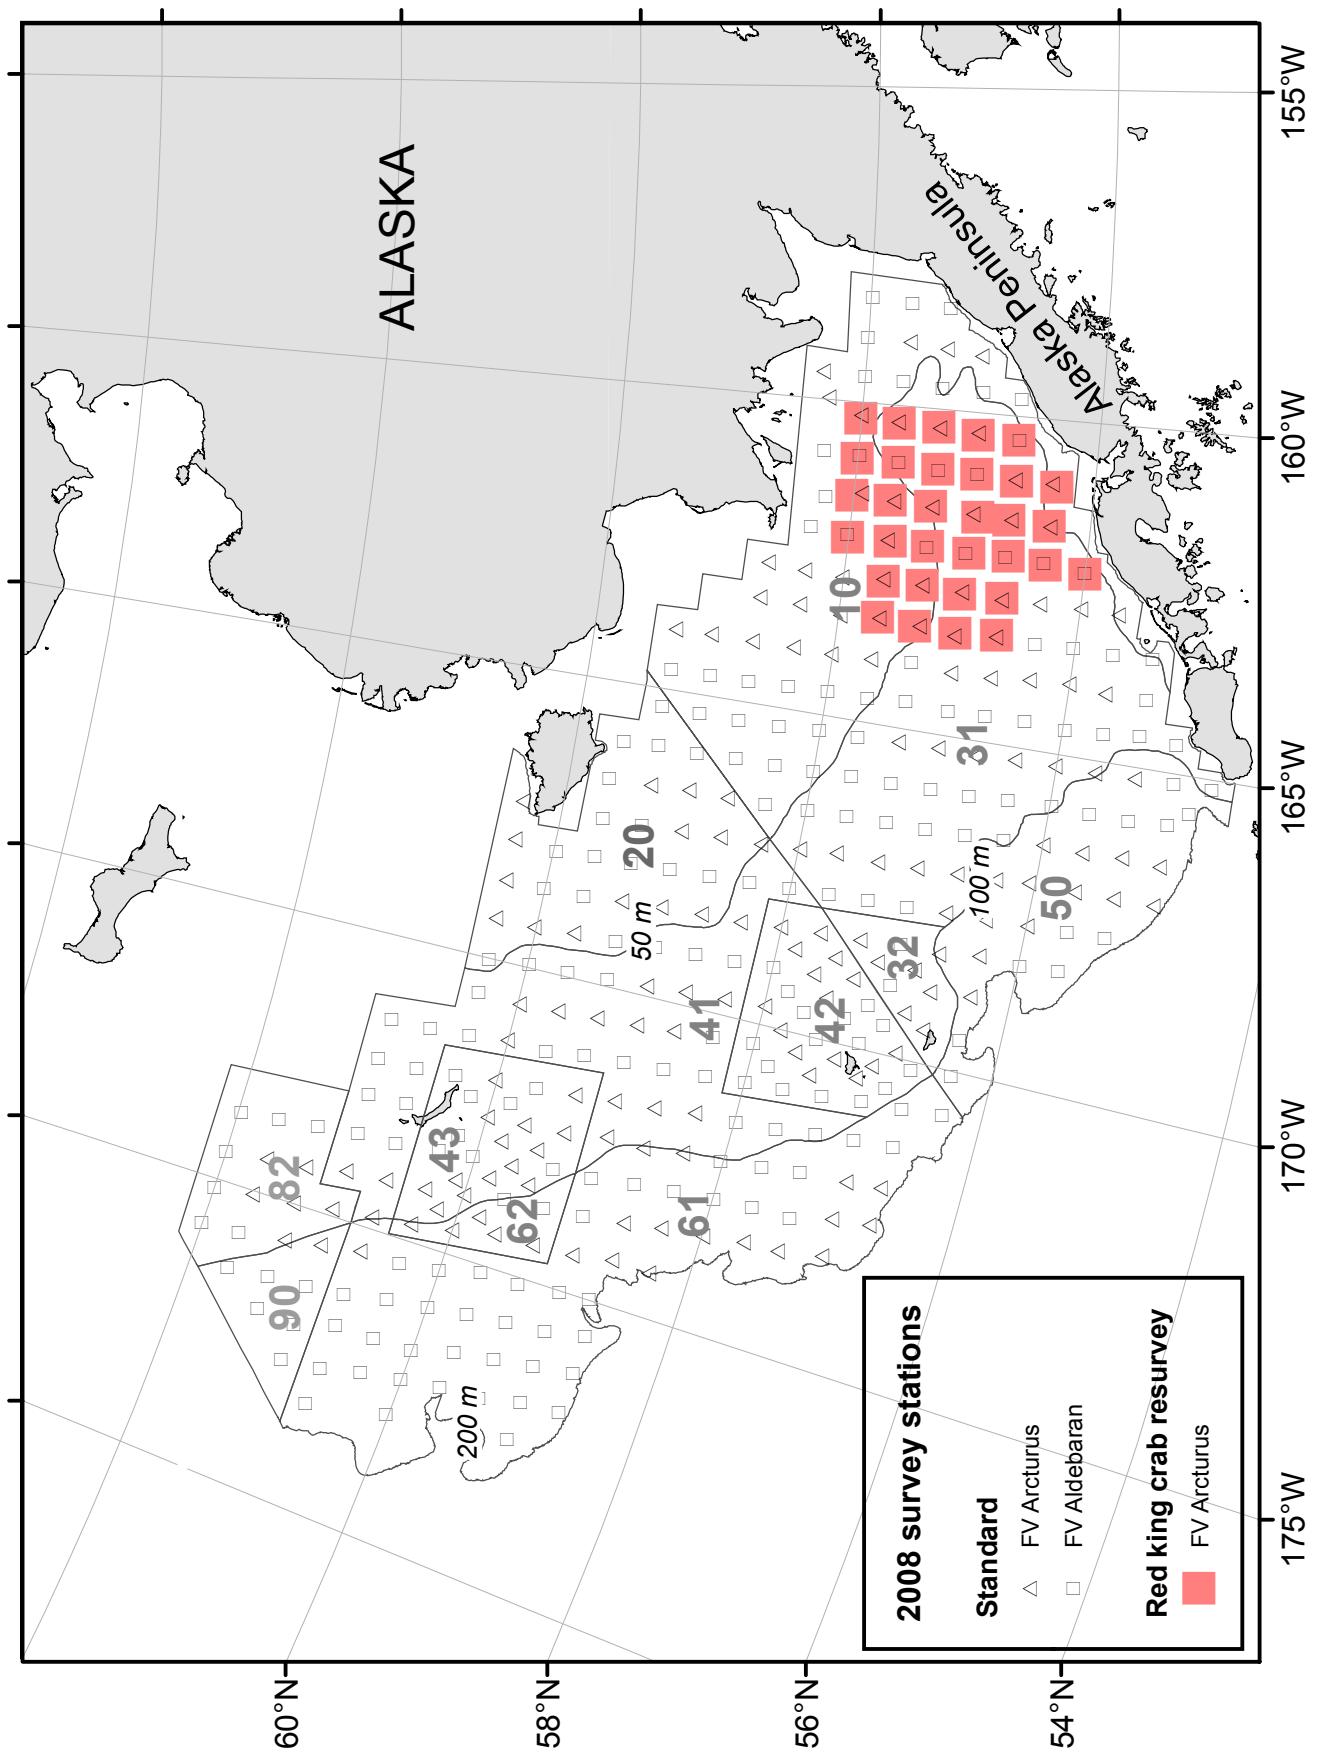

Figure 2. -- Sampled survey stations by vessel and the stratification scheme used for data analysis of the 2008 eastern Bering Sea bottom trawl survey.

For catch analysis, the survey region was divided into six strata bounded by the 50-m, 100-m, and 200-m isobaths and into two geographic strata that separate the northwest and southeast portions of the study area (Fig. 2). This stratification scheme best reflects the differences observed in Bering Sea groundfish across the different oceanographic domains, and the intention of the design was to reduce the variances of population and biomass estimates (Bakkala 1993). Localized high-density sampling for blue king crab in Strata 30, 40, and 60 necessitated a further subdivision into high-density and standard-density sample strata, resulting in a total of 12 strata.

The overall sampling density for the entire survey area was one station per 1,322 km² (Table 1). However, because of the high-density sampling in Strata 30, 40, and 60, and the irregular stratum boundaries, sampling density within the 12 subdivided strata varied from one station per 775 km² (Stratum 42) to one per 1,721 km² (Stratum 82).

Survey Vessels and Sampling Gear

From 30 May to 28 July 2008, the survey was conducted aboard the chartered commercial stern-trawlers FV *Arcturus* and FV *Aldebaran*. All fishing operations were conducted in strict compliance to national and regional protocols detailed in Stauffer (2004). Both vessels were equipped with standard 83-112 Eastern otter trawls, which have 25.3-m (83 ft) headropes and 34.1-m (112 ft) footropes (Fig. 3). These nets were attached to tail chains with 54.9-m (30 fathom) paired dandylines. Each lower dandyline had a 0.61-m chain extension connected to the lower wing edge to improve bottom-tending characteristics. Steel "V"-doors measuring 1.8 × 2.7 m and weighing 816 kg each were used.

83/112 EASTERN

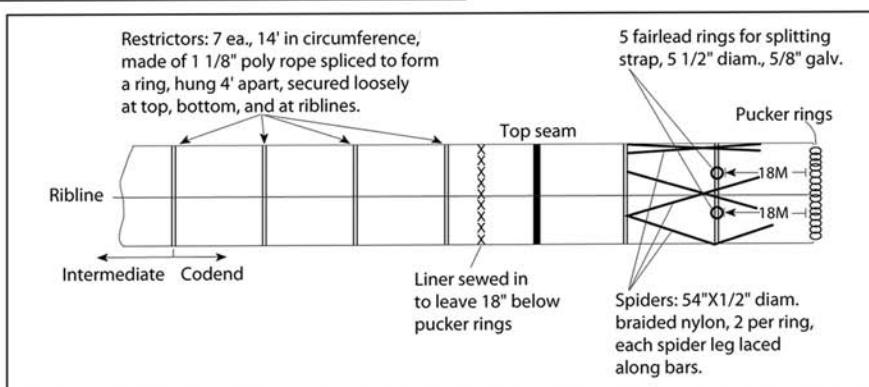

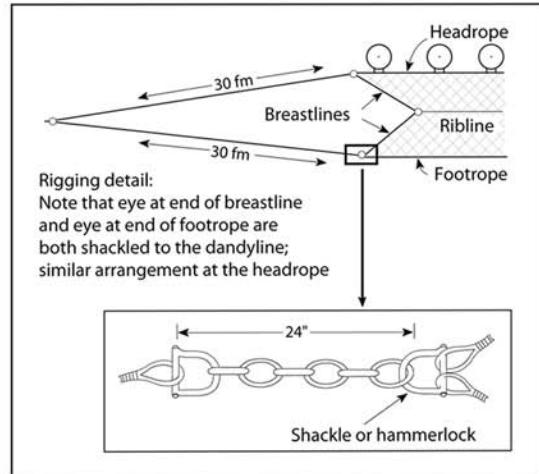

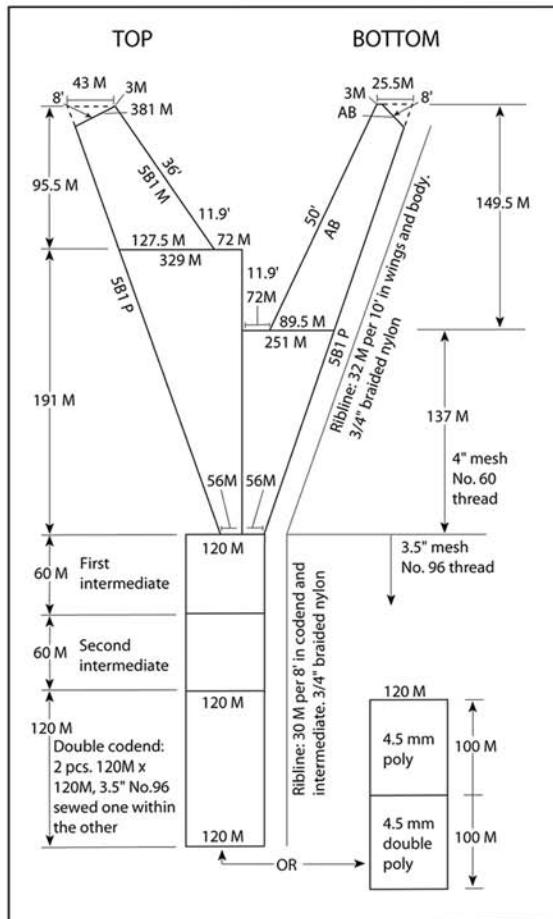

Figure 3. -- Schematic diagram of the 83/112 Eastern otter trawl gear used during the 2008 eastern Bering Sea bottom trawl survey

Netmind net mensuration systems (Northstar Technical Inc., St. John's, Newfoundland) were used aboard each vessel to monitor and record net height and width during fishing operations. Net width was measured as the distance between two sensors attached to the upper starboard and port dandylines, about 0.61 m in front of the net, and net height was measured from the headrope to the seafloor bottom. Estimates of mean net width were used in calculations of the area-swept per tow (Rose and Walters 1990). For tows without observed net width values, a mean net width-inverse scope regression (Zar 1999) was used because it accounts for a majority of the variation for the eastern Bering Sea standard survey trawl (Rose and Walters 1990; Fig. 4).

Catch Sampling Procedures

Detailed sampling procedures used in RACE eastern Bering Sea assessment surveys are described in detail by Wakabayashi et al. (1985) and Stauffer (2004). A brief summary of these procedures is described below.

Samples were collected by trawling near the center of each grid square (or corner station, in the case of high-density strata) for a target fishing time of 30 minutes and towing at a speed of 1.54 m/sec (3 knots). If the seafloor appeared to be untrawlable at the specified location, the nearest trawlable site within the same grid square was used. If the net was damaged or the net impacted by bottom structure during the trawl, the catch was discarded and a new sample obtained.

Catches estimated to be less than approximately 1,150 kg (2,500 lb) were typically enumerated entirely while larger catches were subsampled. After sorting the subsample,

individual species were weighed in aggregate and counted and these weights and numbers were expanded to the total catch.

Fishes and invertebrates were identified and sorted to the lowest taxonomic level practicable. Similar morphological features between flathead sole (*Hippoglossoides elassodon*) and Bering flounder (*H. robustus*) make accurate identification of these species difficult in areas where the two species overlap; thus, in the analysis for this report these species are grouped by genus (*Hippoglossoides* spp.). Due to low abundance (believed to be < 1%) of southern rock sole (*Lepidopsetta bilineata*) and its morphological similarities to northern rock sole (*L. polyxystra*; Orr and Matarese 2000), these species were also grouped by genus (*Lepidopsetta* spp.) for this report.

Catch weights and numbers by species or species group were either estimated directly when subsampled, or estimated by extrapolating the proportion in the subsample to that of the entire catch weight. All Pacific halibut (*Hippoglossus stenolepis*), Greenland turbot (*Reinhardtius hippoglossoides*), skates, and commercial crab species were weighed and enumerated from each catch. Other fish species (such as certain sculpins, rarely encountered species, sharks) may have been completely sorted from the catch as well.

Random samples of approximately 200 fish of each selected abundant species from each haul were used for length measurements. Size composition data were collected for each commercially important groundfish species and many co-occurring species (Table 2). The sex of each specimen was determined then each was measured to the nearest centimeter (fork length measurement). Unless retained for sampling by the International Pacific Halibut Commission (IPHC) for management purposes, Pacific halibut were measured upon capture and immediately

returned to the sea in an effort to reduce mortality; weights were estimated using an IPHC regression.

Sagittal otoliths were collected from 14 fish species in both the northwestern and southeastern divisions of the survey area (Table 3). The eastern Bering Sea was divided into low and high-density strata for walleye pollock otolith sampling based on historical density data and a depth contour of approximately 70 m. Otoliths were collected from all hauls in which the total number of walleye pollock was 20 or more. Walleye pollock samples for otolith collection were selected at random from fish samples prior to sex determination. Six pairs of otoliths were collected in high-density strata and four in low-density strata. If walleye pollock length samples were stratified by size (i.e., separated into juveniles and adults before measuring), two of either the four or six otolith pairs were taken from juveniles.

Three otolith pairs per sex-centimeter interval per vessel (six pairs total) were collected for Pacific cod, arrowtooth flounder (*Atheresthes stomias*), starry flounder (*Platichthys stellatus*), Greenland turbot, Bering flounder, and bigmouth sculpin (*Hemitripterus bolini*). Five otolith pairs per sex-centimeter interval by vessel (10 pairs total) were collected for yellowfin sole. Northern rock sole, flathead sole, and Alaska plaice (*Pleuronectes quadrituberculatus*) were also collected at five otolith pairs per sex-centimeter interval, but on only one vessel. Pacific halibut otoliths were collected aboard the FV *Aldebaran* by the IPHC for population and growth analyses, and Alaska skate (*Bathyraja parmifera*) vertebrae were collected aboard the FV *Arcturus*.

Individual fish weights were collected for all species for which age structures were taken. Otoliths for roundfish were preserved in 70% ethanol, flatfish otoliths were preserved in 50% glycerol-thymol solution, and skate age structures (vertebrae) were frozen.

^aSkate vertebrae were collected for ageing.

^bInternational Pacific Halibut Commission (IPHC) manages and analyzes age structure collection.

Surface and bottom water temperatures, as well as temperature and depth profiles, were recorded at 1-second intervals at each station using a Sea-Bird SBE-39 datalogger (Sea-Bird Electronics Inc., Bellevue, WA) attached to the headrope of the trawl. Depth to bottom was obtained by adding net height to headrope depth.

Catch Data Analysis

Trawl survey catch data were used to estimate: 1) relative abundance; 2) population biomass; 3) population numbers, and 4) population abundance by size class. A brief description of the procedures used in the analysis of RACE Bering Sea survey data follows (for a detailed description see Wakabayashi et al. 1985). Note: some of the species collected were grouped by family for catch data analysis because of their limited commercial value or uncertain identification.

Mean catch per unit effort (CPUE) values for each species were calculated in kilograms per hectare ($1 \text{ ha} = 10,000 \text{ m}^2$) and number per hectare for each of the 10 strata; area swept (hectares) was computed as the distance towed multiplied by the mean net width (Alverson and Pereyra 1969). Mean CPUE values were calculated for individual strata and for the overall survey area. Biomass and population estimates were derived for each stratum by multiplying the stratum mean CPUE by the stratum area. Stratum totals were then summed to produce estimates for each of the six main strata and the total survey area.

For size composition estimates, the proportion of fish at each length interval (from subsamples at each station), weighted by CPUE (number of fish/ha), was expanded to the stratum population. Stratum estimates were summed to derive the estimated size composition for each of the six main strata and for the overall survey area.

Except for Pacific halibut, otolith samples collected during the survey were read for age estimates by staff of the Age and Growth Program of the AFSC's Resource Ecology and Fisheries Management (REFM) Division. Age, growth, and population analyses will be presented in separate reports (e.g., Ianelli et al. 2008).

Additional Research Projects

In addition to the survey operations, there were 18 research projects undertaken during 2008 (Table 4). The RACE Division projects included studies of: 1) acoustic data collection for augmenting the midwater assessment of walleye pollock; 2) fish behavior in response to light and vessel noise; 3) fish and crab reproduction and pathology; 4) summer zooplankton biomass; 5) octopus taxonomy and morphometrics; 6) characterization of the benthic infauna community, and 7) king crab population genetics. The REFM Division and the AFSC's Auke Bay Laboratories (ABL) special studies projects included: 1) fish stomach scans and collections (Table 5); 2) a short-tailed albatross survey; 3) seasonal energy reserves of gadoids; 4) tagging of Alaska skates; 5) energy content and diet of forage fishes; 6) snailfish taxonomy and food habits; 7) tissue collections for a DNA-based identification library, and 8) voucher specimen collections. Projects from outside the AFSC involved: 1) halibut otolith, tag and size collections by the IPHC; 2) reproductive potential of snow and Tanner crabs by the ADF&G; 3) collection of biological and oceanographic data for the Bering Sea Integrated Ecosystem Research Program (BSIERP) and the Pacific Marine Environmental Laboratory (PMEL), and 4) collection of data by University of Alaska Seward (UAS) to develop a reproductive index for male snow crab.

Yellowfin sole	260
Total	6,730

Results and Discussion

A total of 375 stations were successfully sampled in 2008 and one station was abandoned in 2008 after several repeated attempts resulted in gear damage (Fig. 2). Any hauls that experienced significant gear damage or debris such as discarded crab pots were re-sampled immediately following the original haul. Haul data for successfully trawled stations used in the analyses are listed in Appendix B along with the relevant information about each station such as position, tow parameters (net width, depth, distance fished, and duration of haul), time, and environmental measurements (surface and gear temperatures) for each vessel.

After the FV *Arcturus* completed the standard survey sampling in mid-July, it returned to Bristol Bay to resample 32 stations for female red king crab (Fig. 2). It was necessary to resample the stations because the female red king crab had not yet molted and extruded their eggs when the stations were first sampled in early June. An accurate estimate of the abundance of molted and spawned female red king crab is critical to managers for determining if the red king crab population is overfished.

Ocean Conditions

Sea surface temperatures recorded during the survey ranged from 0° to 8.1°C (Fig. 5). As in most previous surveys, surface temperature increased from east to west across the shelf, reflecting the progression of summer warming as the survey proceeded. Sea bottom temperatures ranged from –1.7° to 4.4°C (Fig. 6). Warmer bottom temperatures (above 3.0° C) occurred along the inner shelf from the northern portion of Bristol Bay to Nunivak Island, and most of the outer shelf west of the 100 m contour. Again in 2008, a cold pool (<2°C) occupied most of the

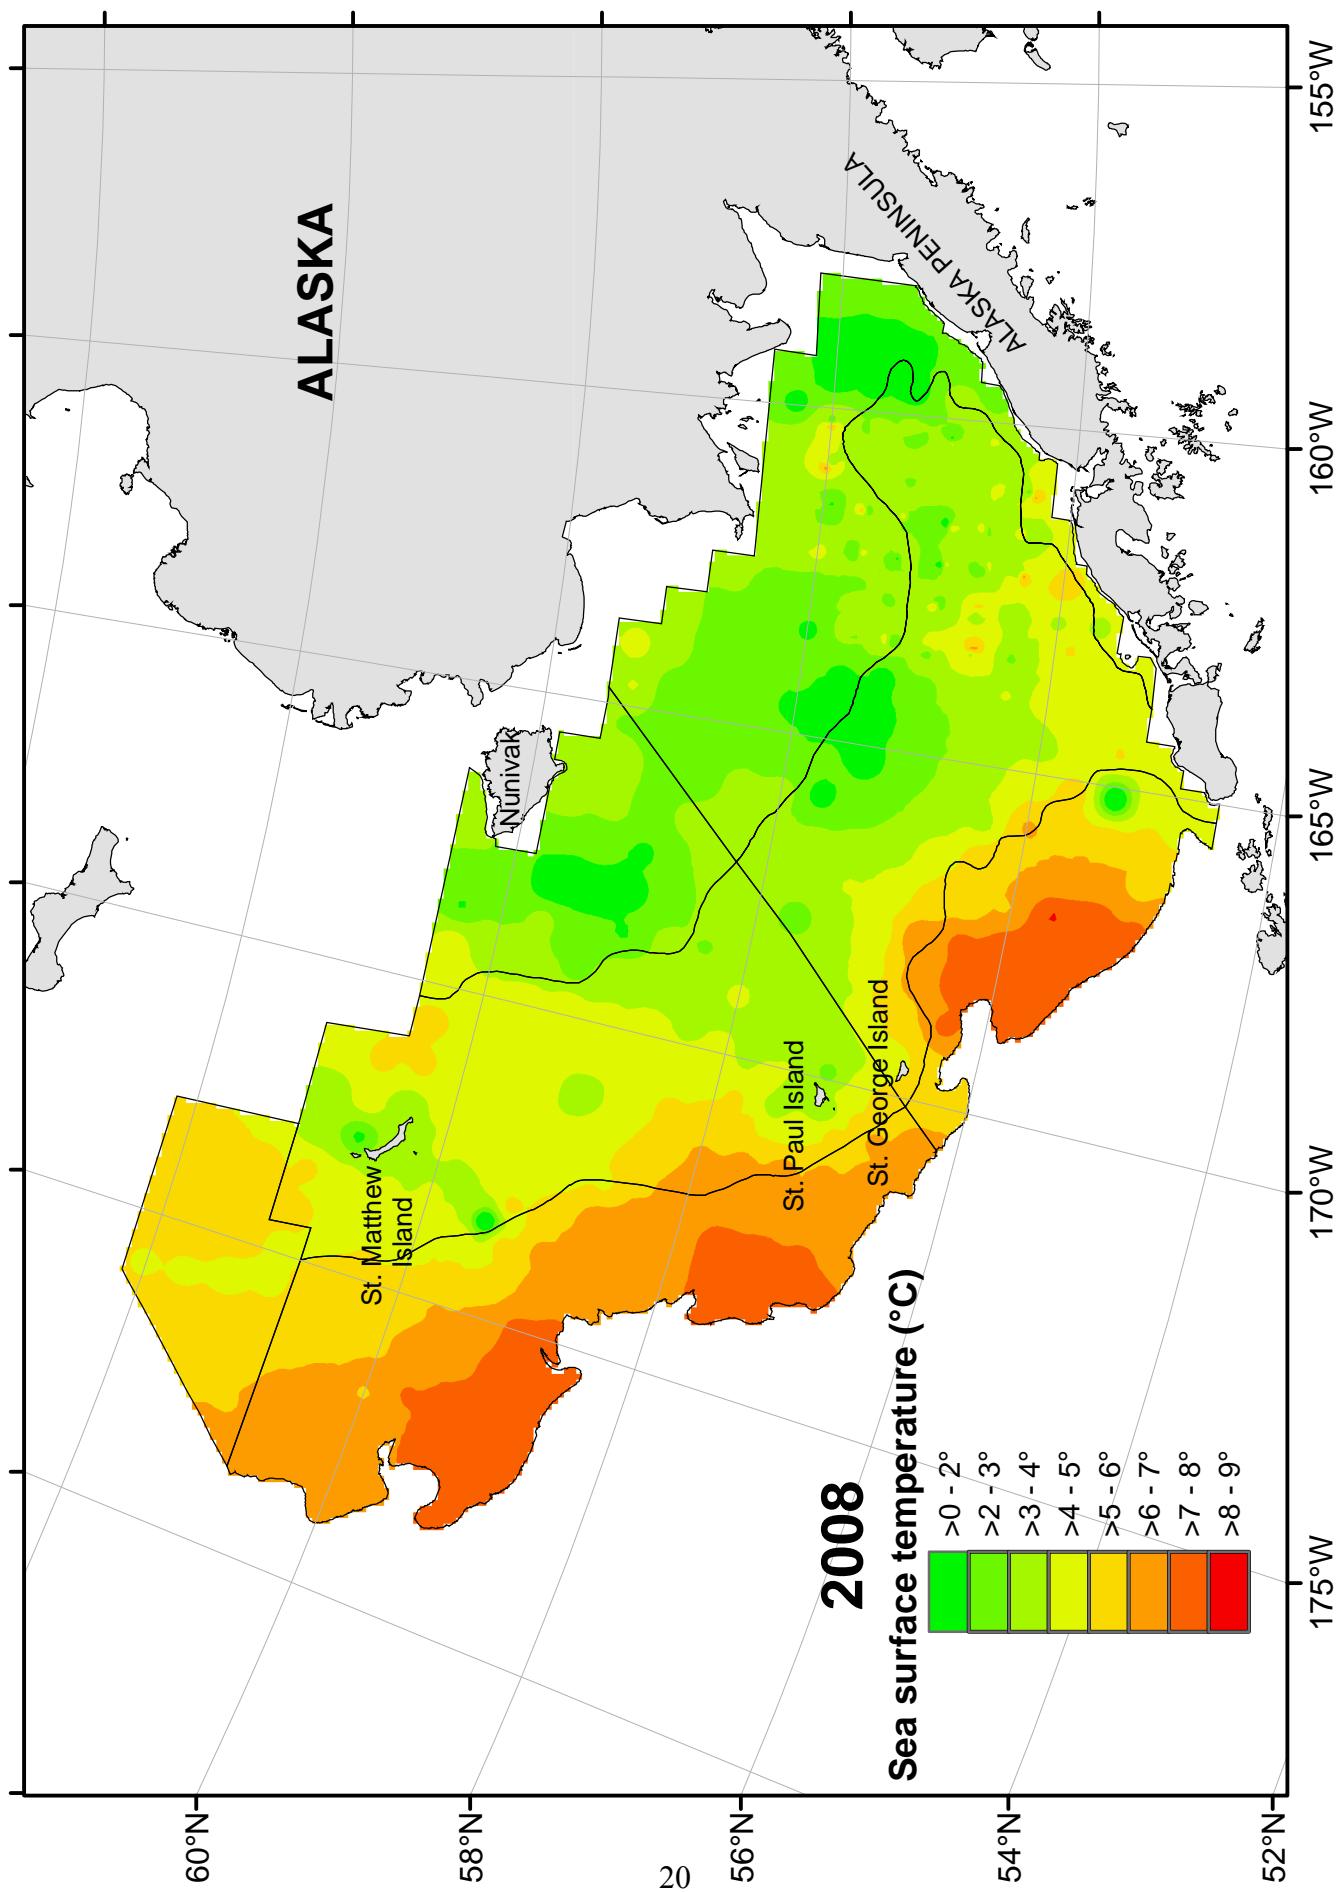

Figure 5. -- Distribution of sea surface water temperatures ($^{\circ}\text{C}$) observed during the 2008 eastern Bering Sea bottom trawl survey.

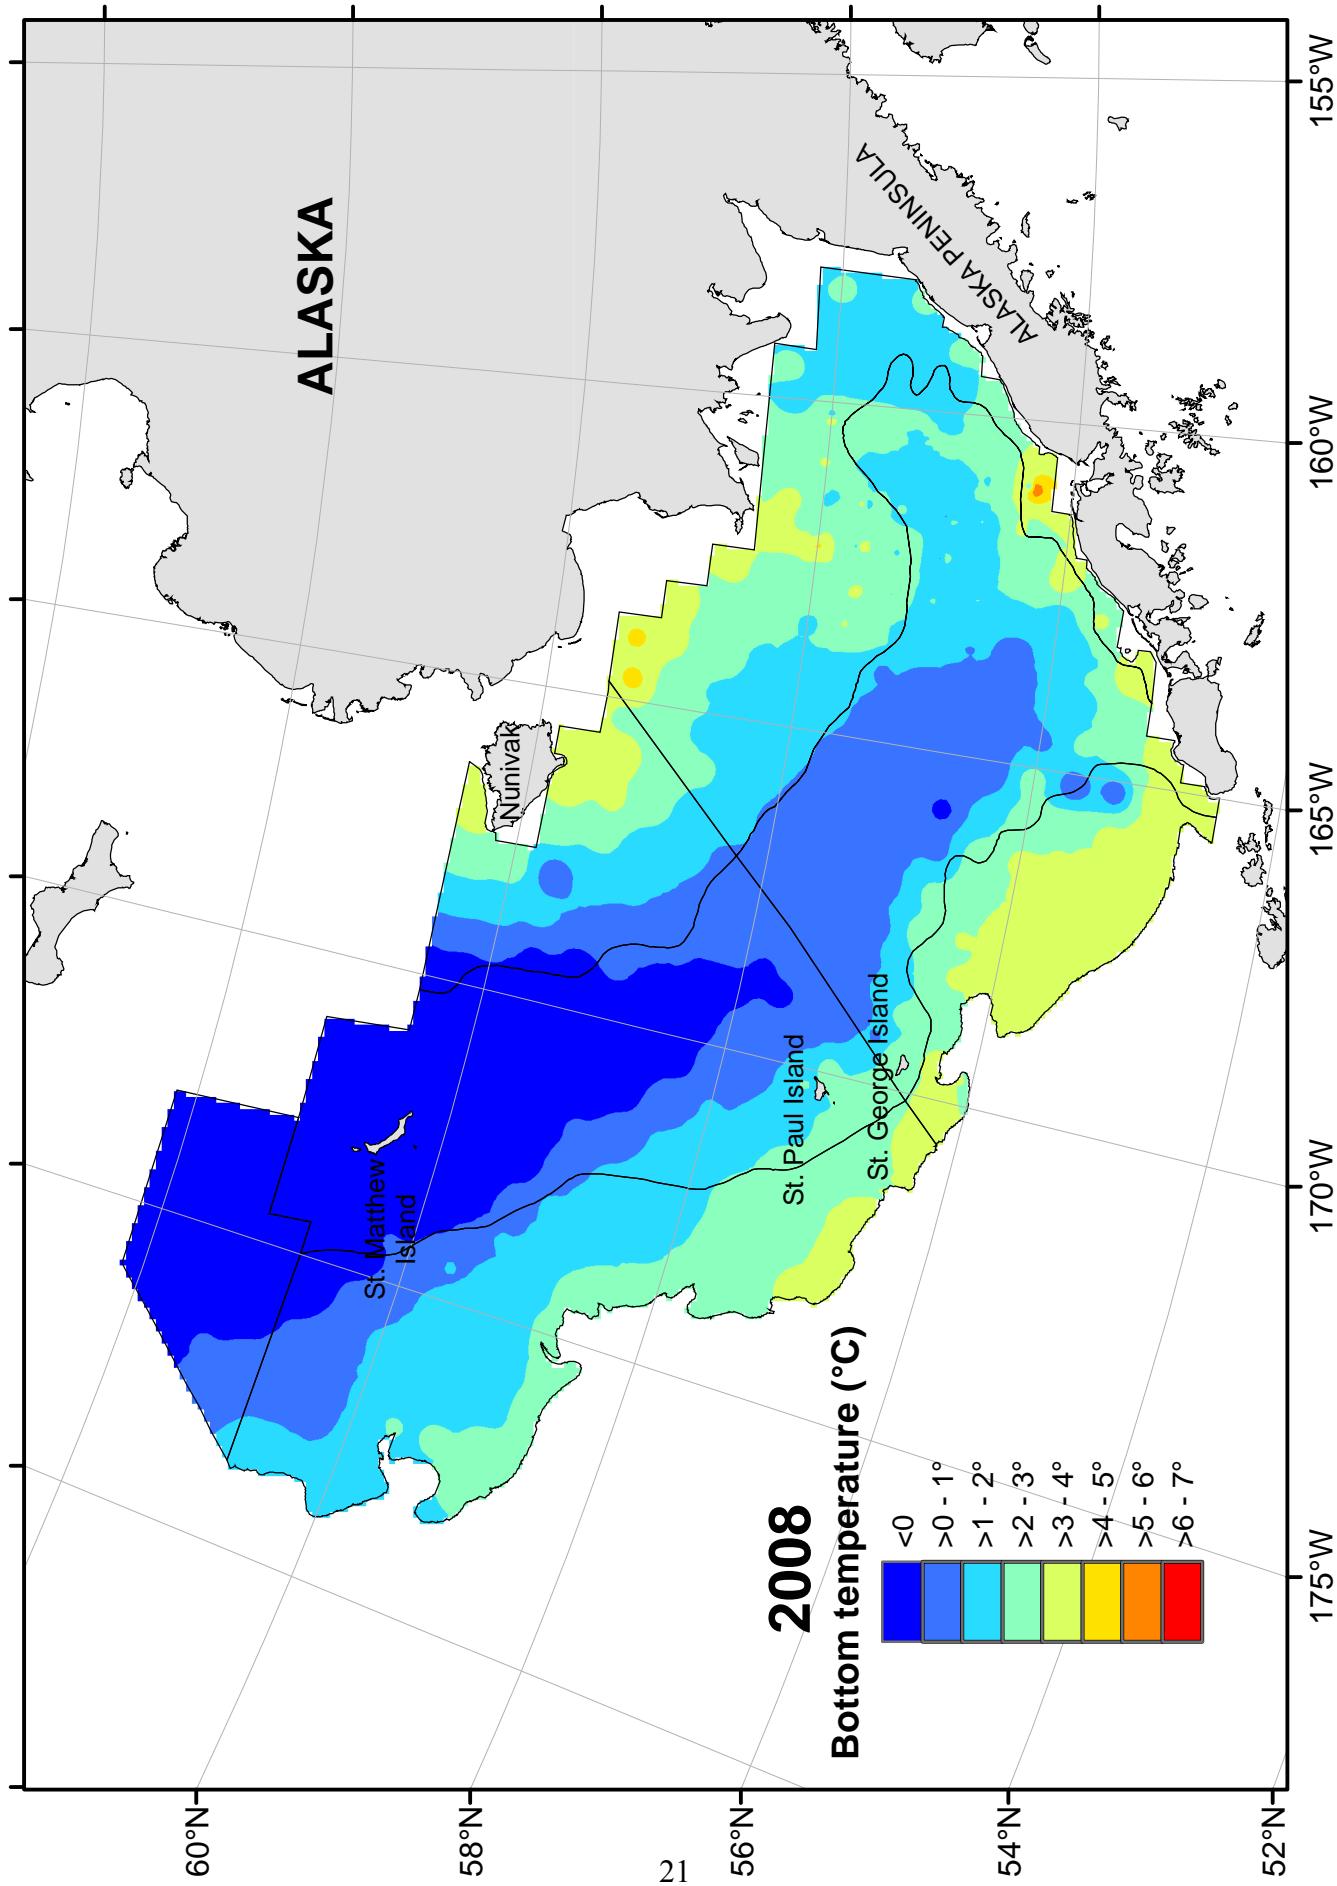

Figure 6. -- Distribution of bottom water temperatures (°C) observed during the 2008 eastern Bering Sea bottom trawl survey.

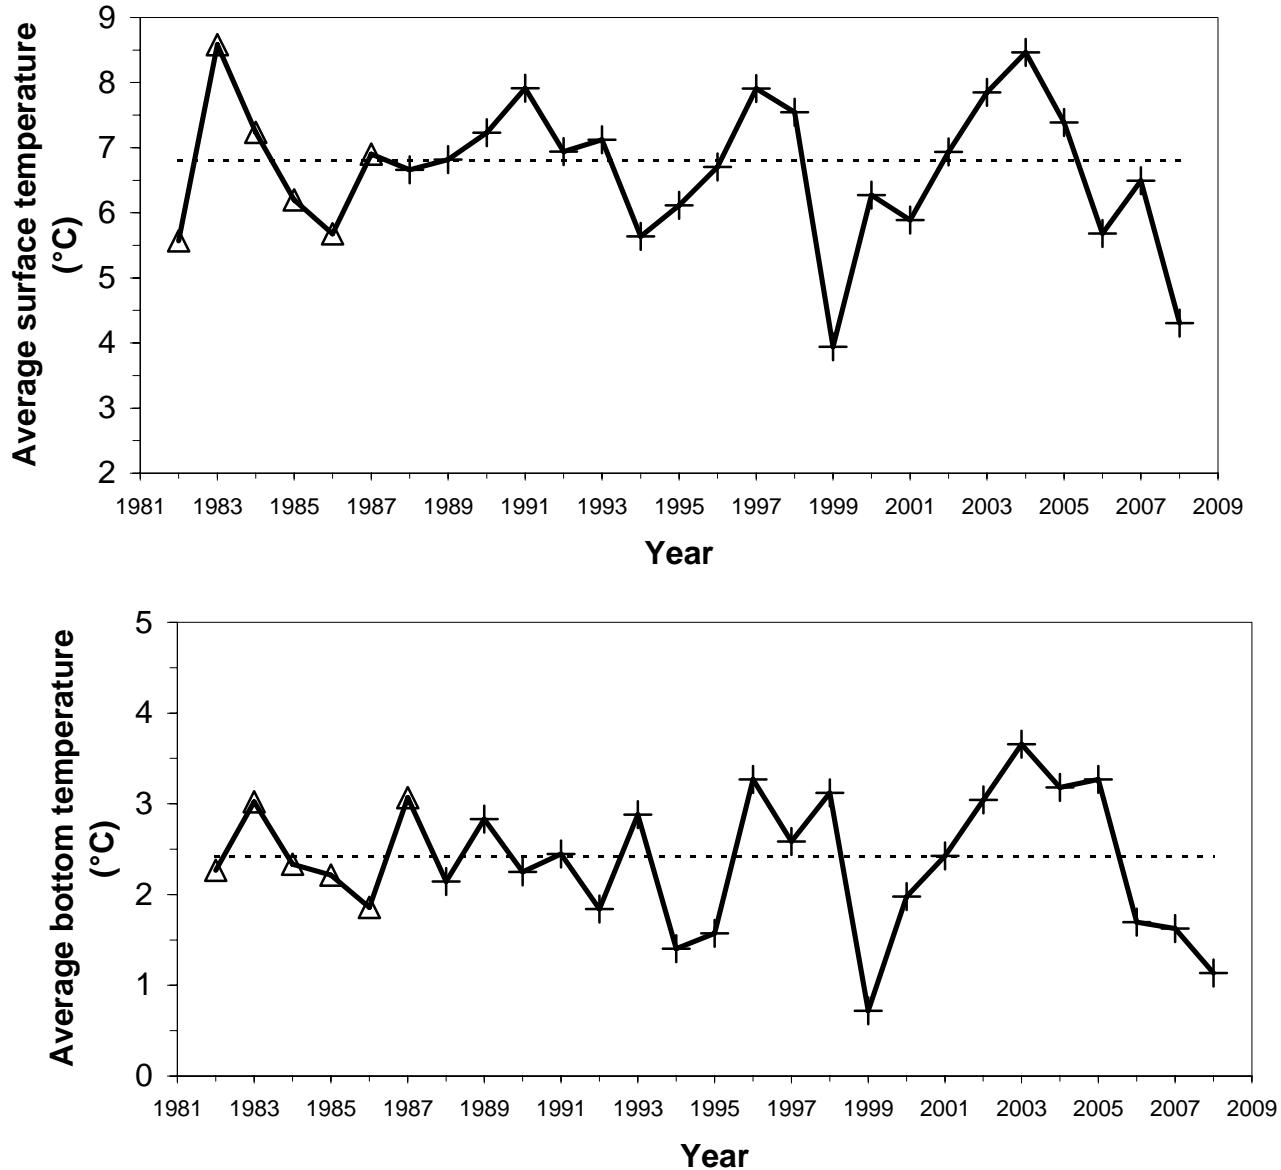

Figure 7. -- Mean survey surface and bottom temperatures weighted by stratum based on expendable bathythermograph casts or digital dataloggers attached to the headrope during the eastern Bering Sea bottom trawl surveys from 1982-2008. The 1982-1987 means (triangles) are based on the standard survey area (see Fig. 1) and the 1988-2008 means are based on the expanded survey area. The dashed lines represent the grand mean water temperatures for 1982-2007.

mid-shelf at depths between 50 and 100 m and extended south to the Alaska Peninsula and into Bristol Bay.

Average surface (4.3°C) and bottom (1.1°C) water temperatures were lower than 2007, and below the long-term mean from 1982 to 2007 for the surface (6.8°C) and for the bottom (2.4°C ; Fig. 7).

Relative Fishing Powers of Survey Vessels

Historically, two vessels have been used to conduct the eastern Bering Sea shelf bottom-trawl survey, and fishing power corrections (FPC) have been applied when statistical differences of mean CPUE values were detected between the two vessels (Kappenman 1992). In 2006, application of an FPC was discontinued because of concerns that it was not correcting for vessel effect but was increasing the overall error in CPUE estimates. The underlying assumption for using an FPC was that one survey vessel was less efficient at sampling than the other survey vessel and that systematic error caused by vessel effects warranted correction (Munro 1998).

Table 6 lists the calculated FPCs, by fish species, which were applied to CPUE estimates for the less-efficient survey vessel for survey years 1982-2005. Concerns about using an FPC were raised by studies showing that overall error in CPUE estimates can actually increase unless there are substantial differences between vessels (Munro 1998). Survey gear research done by the AFSC (Somerton and Weinberg 2001, Weinberg 2003, Kotwicki and Weinberg 2005, Kotwicki et al. 2006, Weinberg and Somerton 2006, Weinberg and Kotwicki 2007) and real time monitoring and data collection of trawl and vessel performance (Zimmerman et al. 2003) has increased our awareness and helped us to reduce possible systematic errors associated with “vessel effects”. Moreover, a detailed investigation of our methodologies used for post-

Table 6. -- Calculated fishing power corrections (FPC) applied to CPUE estimates by fish species for the "less-efficient" survey vessel for survey years 1982-2005.

processing of data and area-swept calculations revealed systematic errors that may have otherwise been attributed to vessel effects.

Another reason why the overall error of FPC-adjusted CPUE estimates was probably artificially high was nonrandom selection of stations from alternate columns for calculating the FPC. Without random selection of stations, it was possible that observed differences between vessels were actually real differences in fish distribution and abundance. For example, the location and timing of the cold pool on the eastern Bering Sea shelf has a dramatic effect on fish distribution, so if one vessel is sampling a column inside the cold pool and the other is sampling in the adjacent column outside the cold pool, differences in catch rates between the two vessels may be due to the effect of the cold pool on fish distribution rather than a vessel-effect.

The RACE Groundfish Assessment Program is continuing to investigate sources of systematic error and to devise methods for minimizing systematic error in area-swept calculations (Stan Kotwicki, AFSC; personal communication). Before these new methods can be implemented, it will be necessary to reconcile historical data and complete the development of a new relational database for accessing stream data for doing area-swept calculations. Until this can be accomplished, application of an FPC adjustment will not be done; however, so as not to affect the historical time series, FPC adjustments made to catches prior to 2006 will remain unchanged.

Relative Abundance

The relative abundance of the 11 most abundant species and species groups of fishes are presented in Figure 8. These taxa accounted for 63% (199 kg/ha) of total catch mean CPUE

Relative abundance

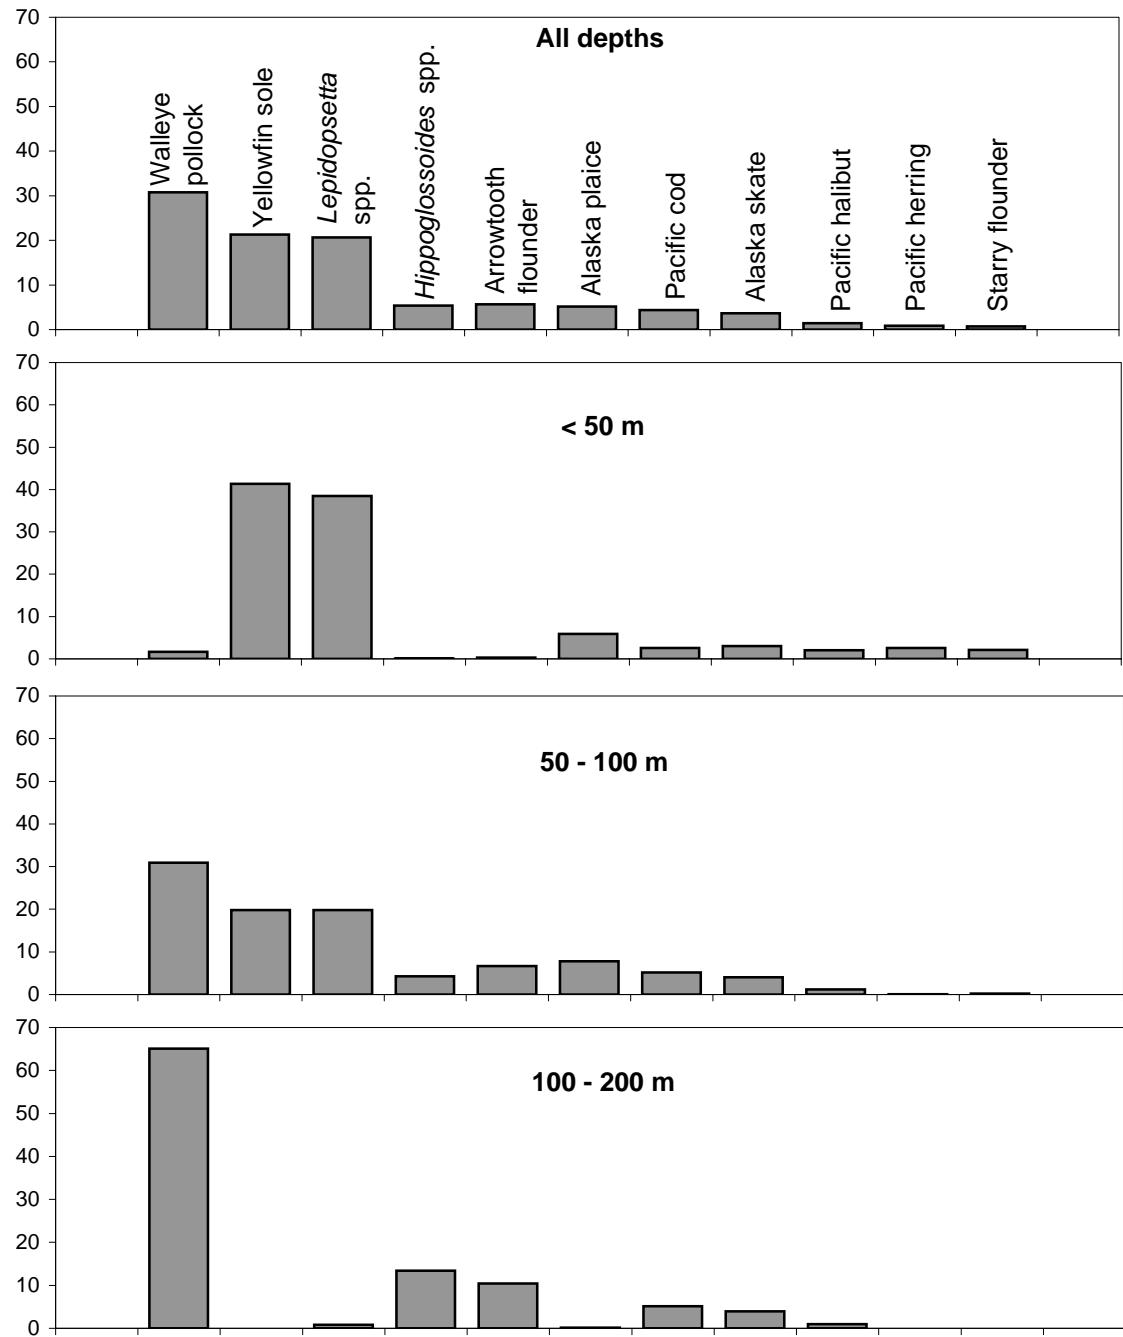

Figure 8. -- Relative abundance (%CPUE in kg/ha) of principal groundfish species (top 11 for all depths combined) by depth zones and for all depths combined for the 2008 eastern Bering Sea bottom trawl survey.

(316 kg/ha) and 84% of total fish mean CPUE (237 kg/ha). The walleye pollock mean CPUE for all areas combined was 61.2 kg/ha. Walleye pollock was the dominant groundfish species at depths between 50 and 200 m. This species was encountered at nearly all sampling stations, with the largest mean catches observed in the outer shelf stations. Pacific cod were also caught primarily in the 50-200 m depth zone with an overall mean CPUE of 8.7 kg/ha. Rock sole, as well as yellowfin sole, with overall mean catch rates of 41.0 and 42.4 kg/ha, respectively, were abundant in water less than 50 m. See Appendix C for a descending rank of all organisms caught.

Biomass, Abundance, Distribution, CPUE, and Size Composition of Principal Species and Species Groups

A total of 83 species of fishes representing 19 families and 54 genera were identified in the catches from the entire survey area (Appendix A1). In addition, a total of 272 individual invertebrate taxa were identified from 12 phyla with 174 identified to the species level (Appendix A2).

Total demersal animal biomass for the standard survey area was estimated at 14.3 million t, of which fish species accounted for 76% (10.8 million t; Table 7) and invertebrates 24% (3.5 million t; Table 8). Greatest concentrations of fish biomass were located in Bristol Bay, along the Alaska Peninsula, around the Pribilof Islands, and in the outer shelf northwest of the Pribilofs (Fig. 9). The fish biomass was dominated by pleuronectids (6.6 million t) and gadids (3.5 million t; Table 7). The biomass of invertebrates was composed primarily of echinoderms (1.6 million t) and crustaceans (0.75 million t; Table 8).

Geographic distributions, population numbers, biomass estimates, and size composition are presented in Figures 9 - 48 and Tables 9 - 28 for each of the following eastern Bering Sea groundfish: walleye pollock; Pacific cod; yellowfin sole; northern and southern rock sole grouped; flathead sole and Bering flounder grouped; Alaska plaice; Greenland turbot; arrowtooth flounder; Kamchatka flounder (*Atheresthes evermanni*); Pacific halibut; starry flounder; Bering skate (*Bathyraja interrupta*); Alaska skate; warty sculpin (*Myoxocephalus verrucosus*); great sculpin (*M. polyacanthocephalus*); plain sculpin (*M. jaok*); bigmouth sculpin; wattled eelpout (*Lycodes palearis*); shortfin eelpout (*L. brevipes*), and marbled eelpout (*L. raridens*). Estimated biomass and population numbers are given separately for each of the 12 geographic strata used in the analysis (see Table 1) and for the entire survey area. Size compositions are illustrated in histograms relating the population percentage by 1 cm length interval for each stratum and in population numbers for the total survey area. Catch per unit effort (CPUE), population, and biomass estimates and associated variances and confidence limits are listed for each species by stratum. All results except size composition are presented for sturgeon poacher (*Podothecus accipenserinus*), Bering poacher (*Occella dodecaedron*), butterfly sculpin (*Hemilepidotus papilio*), eulachon (*Thaleichthys pacificus*), capelin (*Mallotus villosus*), Pacific herring (*Clupea pallasi*), and Arctic cod (*Boreogadus saida*) in Figures 50-56 and Tables 29-35.

Appendices to the report contain detailed results of the survey including population estimates by sex and size class, and rank of fish and invertebrate taxa by unweighted total CPUE (kg/ha). A more detailed explanation of results follows for the 10 fish species (or grouped species) that are commercially exploited on the eastern Bering Sea shelf.

Summary of Results for Commercially Exploited Groundfish Species

Walleye Pollock (*Theragra chalcogramma*)

Walleye pollock were captured at 89% of the standard survey stations (Fig. 10). Catch rates were lowest on the inner shelf compared to the middle and outer shelf. The highest densities were north of the Alaska Peninsula, around the Pribilof Islands, and along the northwest outer shelf (Fig. 10). The total biomass and abundance of walleye pollock for the entire survey area was 3.03 million t and 3.97 billion fish with an average weight per walleye pollock of 0.76 kg (Tables 10a and 10b) and average length of 44.7 cm (Fig. 11). The 2008 biomass estimate was lower than the 2007 estimate of 4.3 million t but equal to the 2006 estimate of 3.0 million t (Ianelli 2008 et al.). Besides general year-class variability, this lower estimate may in part be due to a shift of the population to the shelf edge or a change in the vertical distribution pattern of pollock caused by the colder than average water temperatures on the Bering Sea shelf during 2008 (Ianelli et al. 2008, Kotwicki et al. 2005). One-year-olds, represented by the modal length of 10-15 cm, had the highest abundance on the inner shelf relative to the outer shelf, where larger pollock dominated (Fig. 11). The mode for the population of 1-year-olds peaked at about 100 million in 2008 compared to a mode for 1-year-olds that peaked at a little over 400 million in 2007. Although we might expect to see more age-2 pollock (modal length of 15-25 cm) following the high number of 1-year-olds in 2007, the relatively low abundance of age-2 pollock was not surprising given that they are generally under-represented in survey trawl catches.

Pacific Cod (*Gadus macrocephalus*)

Like walleye pollock, Pacific cod were also broadly distributed across the shelf being observed in 91% of the trawls (Fig. 12). The highest catch rates of Pacific cod were observed in the northwestern strata of the middle and outer shelf, especially between St. Matthew Island and the Pribilof Islands (Tables 10a and 10b; Fig. 12). The 2006 year class (modal length of 20-40 cm) was dominant in the 2007 survey as 1-year-olds and again in 2008 as 2-year-olds, and they were widely distributed across the shelf (Fig. 13).

Yellowfin Sole (*Limanda aspera*)

Yellowfin sole catch rates were highest on the inner shelf and decreased to little or nothing on the outer shelf, except in the vicinity of St. Matthew Island and the Pribilof Islands (Tables 11a and 11b; Fig. 14). The biomass and population estimates for yellowfin sole changed very little from 2007: the biomass decreased slightly from 2.2 to 2.1 million t and the population size increased slightly from 8.5 to 8.9 billion. Yellowfin sole with a modal length of 10-25 cm were only found on the inner shelf and those with a modal length from 25-40 cm were found both on the inner and middle shelf (Fig. 15). Yellowfin sole undergo a spring migration from the shelf-slope break onto the inner shelf each year for spawning and feeding (Nichol 1998). The group of smaller yellowfin sole on the inner shelf probably represent the juveniles less than 6 years of age that overwinter in the nearshore (Nichol 1997).

^bProportion of total estimated biomass, fish and invertebrates combined, for the total survey area = 15,425,051 t.

Northern and Southern Rock Sole (*Lepidopsetta* spp.)

The distribution and abundance of rock soles was very similar to that of yellowfin sole (Tables 12a and 12b; Fig. 16). Estimated biomass remained unchanged from 2007 (2.0 million t) and estimated population numbers decreased slightly from 11.0 billion to 10.5 billion (Tables 12a and 12b). Rock sole sizes increased moving from the inner shelf towards the outer shelf (Fig. 17). Spawning and feeding migrations for rock soles are poorly understood, but in general they migrate from shallower summer feeding grounds to deeper winter spawning grounds (Fadeev 1965, Shubnikov and Lisovenko 1964).

Flathead Sole and Bering Flounder (*Hippoglossoides* spp.)

The category “*Hippoglossoides* spp.” represents two species: the flathead sole (*H. elassodon*) and the Bering flounder (*H. robustus*). Although age structures were taken for each of the two species, they were combined in the presentation of results because they are managed as a two-species complex by the NPFMC (Stockhausen et al. 2008) and it facilitates comparisons with previous surveys. Bering flounder are typically more arctic in their distribution compared to flathead sole which is generally distributed in the southeastern half of the shelf. The combined “flathead sole” were distributed on the middle and outer eastern Bering Sea shelf. The highest CPUEs were in the northwest outer shelf, near the Pribilof Islands, and in the southern middle shelf region (Tables 13a and 13b; Fig. 18). Estimated biomass (0.56 million t) and population number (1.9 billion) remained unchanged from 2007 (Tables 12a and 12b). A similar size range of flathead sole (10-50 cm) was observed across the entire shelf (Fig. 19).

Alaska Plaice (*Pleuronectes quadrituberculatus*)

Alaska plaice was most abundant on the inner and middle shelf in waters < 100 m with the heaviest concentrations bordering the 50 m contour (Fig. 20). From 2007 to 2008, the estimated biomass increased from 0.42 million t to 0.51 million t, and the population increased from 0.81 billion to 0.94 billion (Tables 14a and 14b). The larger sizes of Alaska plaice occurred at bottom depths > 50m while smaller juveniles (< 25 cm) at bottom depths < 50 m (Fig. 21).

Greenland Turbot (*Reinhardtius hippoglossoides*)

Greenland turbot is a flatfish species that typically inhabits the upper continental slope, although juveniles may spend several years on the continental shelf (Alton et al. 1988). Greenland turbot were captured in 79 of 355 tows, and most of these tows were in the northwest part of the middle and outer shelf (Fig. 22). Greenland turbot were absent in the inner shelf and in relatively low numbers with a small mean size in the middle shelf strata (Fig. 23). Juveniles are believed to spend the first several years of their life on the shelf before moving to deeper water (Alton et al. 1988). Biomass estimates decreased for the fifth consecutive year from 31.7 thousand t in 2003 to 13.5 thousand t in 2008 (Table 15a); however, the estimated population number of 15.3 million was slightly greater than the 6 year mean of 15.2 million (Tables 15a and 15b).

Arrowtooth Flounder (*Atheresthes stomias*)

Arrowtooth flounder were observed all along the outer shelf and on the middle shelf at bottom depths > 50 m (Fig. 24). Catch rates were generally higher at the deeper more southern stations and very few or no arrowtooth flounder were found in strata along the inner shelf and northern middle shelf (Tables 16a and 16b; Fig. 24). Estimates of both biomass and population size increased in 2008 compared to 2007; biomass increased from 0.48 to 0.53 million t and population from 1.0 to 1.2 billion (Tables 16a and 16b).

Kamchatka Flounder (*Atheresthes evermanni*)

Kamchatka flounder were mostly observed around the Pribilof Islands and along the 100 m contour and outer shelf with the highest catch rates and largest mean size occurring in the northwest (Figs. 26 and 27). Compared to 2007, the biomass decreased from 65 to 58 thousand t and the population decreased from 146 to 120 million fish (Tables 17a and 17b).

Pacific Halibut (*Hippoglossus stenolepis*)

Pacific halibut were widely distributed across the shelf and captured at 81% of the stations, but they were generally absent in trawl catches at or north of 60°N (Fig. 28). Juvenile Pacific halibut with modal lengths < 40 cm were prevalent on the southern inner and middle shelves and the larger adults (> 90 cm) were captured on the outer shelf (Fig. 29). The estimated biomass decreased slightly from 146 thousand t in 2007 to 140 thousand t in 2008 and the population decreased from 120 million to 108 million in the same time period.

Acknowledgments

Recognition and appreciation is extended to the captains and crew of the FV *Aldebaran* and FV *Arcturus*. Without their expertise, goodwill, and sacrifice this survey would not be possible. Thank you to the Trident Corporation for making the vessels available and always maintaining safety as a top priority. Great appreciation is also extended to all the scientists, researchers, and interns who worked tirelessly aboard each vessel to complete the survey in a safe and successful manner. We also thank the survey support team who provided us with technical and scientific equipment. Finally, appreciation is extended to the reviewers of this document whose excellent comments and suggestions greatly improved it.

Appendix B: Station Data, 2008 Eastern Bering Sea Trawl Survey

Appendix B contains station data by vessel for the 375 successfully completed standard survey stations. In using the tables, the following should be noted:

1. Time represents the nearest hour and minute at the start of the haul.
2. Haul numbers are not always sequential because unsatisfactory hauls were omitted.
3. All longitudes are in the Western Hemisphere and latitudes in the Northern Hemisphere. Starting and ending positions for each haul are displayed as degrees and decimal minutes.
4. Net measured codes are as follows:

Y = Net width was measured by net mensuration gear.

N = Net width was estimated from a function of wire out or wire out.

5. Catch weights are displayed in total kilograms

List of Tables

Appendix B Table 1 – Haul data for stations sampled by the FV *Arcturus*.

Appendix B Table 2 – Haul data for stations sampled by the FV *Aldebaran*.

Appendix B Table 1. -- Haul and catch data for successfully completed tows by FV *Arcturus* during the 2008 eastern Bering Sea bottom trawl survey.

Appendix C: Rank Order of Relative Abundance of Fishes and Invertebrates

Appendix C ranks all fishes and invertebrates identified during the 2008 eastern Bering Sea bottom trawl survey by descending unweighted CPUE (kg/ha).

Appendix C Table 1. -- Rank of fish and invertebrate taxa by unweighted total CPUE (kg/ha) from the 2008 eastern Bering Sea bottom trawl survey.

Rank	Species code	Mean CPUE (kg/ha)	Standard error	95% Confidence limits	Proportion	Cumulative proportion	Scientific name
1	21740	61.6758	50.2855	47.7769	75.5746	0.2186	<i>Theragra chalcogramma</i>
2	10260	45.5971	61.6422	30.2087	60.9856	0.1616	<i>Lepidopseta</i> sp.

Appendix D: Population Estimates by Sex and Size Groups for Principal Fish Species

Appendix D presents estimates of the numbers of individuals within the overall survey area by sex and size group for principal fish species.

List of Tables

Population estimates by sex and size group from the 2008 eastern Bering Sea bottom trawl survey.

Appendix D Table 1 – walleye pollock

Appendix D Table 2 – Pacific cod

Appendix D Table 3 – yellowfin sole

Appendix D Table 4 – northern and southern rock sole grouped

Appendix D Table 5 – flathead sole and Bering flounder grouped

Appendix D Table 6 – Alaska plaice

Appendix D Table 7 – Greenland turbot

Appendix D Table 8 – arrowtooth flounder

Appendix D Table 9 – Kamchatka flounder

Appendix D Table 10 – Pacific halibut

Appendix D Table 1. -- Population estimates by sex and size for **walleye pollock** (*Theragra chalcogramma*) from the 2008 eastern Bering Sea bottom trawl survey.
